Q- Two point charges $\mathrm{q}_{1}=(+) 1 \mu \mathrm{C}$ and $\mathrm{q}_{2}=(+) 9 \mu \mathrm{C}$ are separated by a distance of 50 cm .
(a) Find the magnitude and direction of the Coulomb force on each charge due to the other.
(b) At what point on the line joining the two charges should a charge $q=(-) 1 \mu C$ be placed so that the net force on q due to $\mathrm{q}_{1}$ and $\mathrm{q}_{2}$ is zero?
(c) Find the location of charge $q$ for zero force if the charge $q_{2}$ is replaced by a charge of (-) $9 \mu \mathrm{C}$.

If two charges of magnitude $q_{1}$ and $q_{2}$ are separated by distance $r$ then the force between them is given by Coulomb's law and according to this law, the force of interaction between two point charges is given by

$$
\vec{F}_{21}=\frac{q_{1} q_{2}}{4 \pi \in_{0} \in_{r} r^{2}} \hat{r}
$$

Where $F_{21}$ is the force on charge $q_{2}$ due to charge $q_{1}$ and $\hat{r}$ is the unit vector in the direction of the line joining from charge $\mathrm{q}_{1}$ to $\mathrm{q}_{2} . \epsilon_{0}$ is a constant called the permittivity of free space and $\epsilon_{r}$ is the relative permittivity (dielectric constant) of the medium. For air or vacuum,
value of $\epsilon_{r}$ is $1.0, \frac{1}{4 \pi \epsilon_{0}}=9 * 10^{9} \mathrm{Nm}^{2} / \mathrm{C}^{2}$
Naturally the force $F_{12}$ on charge $q_{1}$ due to $q_{2}$ will be equal in magnitude and opposite in the direction.

Now the force acting on charge $\mathrm{q}_{2}$ due to charge $\mathrm{q}_{1}$ will be

$$
\vec{F}_{12}=\frac{q_{1} q_{2}}{4 \pi \epsilon_{0} r^{2}} \hat{r}=9 * 10^{9} * \frac{1 * 10^{-6} * 9 * 10^{-6}}{\left(50 * 10^{-2}\right)^{2}} * \hat{r}=0.324 \hat{r} N
$$

Hence the force on charge $\mathrm{q}_{2}$ is 0.324 N and is towards right. Similarly

$$
\vec{F}_{12}=\frac{q_{1} q_{2}}{4 \pi \epsilon_{0} r^{2}}(-\hat{r})=-9 * 10^{9} * \frac{9 * 10^{-6} * 1 * 10^{-6}}{\left(50 * 10^{-2}\right)^{2}} * \hat{r}=-0.324 \hat{r} N
$$

Hence the force on charge $\mathrm{q}_{1}$ is 0.324 N and is towards left.
(b) The force acting on a point charge due to number of point charges is given by the law of superposition of forces and hence given by the resultant of the forces due to all other charges. Thus the force on q is given by the resultant of the forces due to $\mathrm{q}_{1}$ and $\mathrm{q}_{2}$.

Now as charge $q$ is negative and both the other are positive, both charges attracts $q$ and hence the possibility for the forces on $q$ to balance each other is only when $q$ is between $q_{1}$ and $\mathrm{q}_{2}$. Let q is placed at distance x from $\mathrm{q}_{1}$ as in figure then force on it due to $\mathrm{q}_{1}$ will be

$$
\vec{F}_{1}=\frac{q_{1} q}{4 \pi \in_{0} x^{2}} \hat{r}=9 * 10^{9} \frac{1 * 10^{-6} *\left(-1 * 10^{-6}\right)}{x^{2}} \hat{r}=\frac{9 * 10^{-3}}{x^{2}}(-\hat{r})
$$

And the force due to charge $q_{2}$ will be

$$
\vec{F}_{2}=\frac{q_{2} q}{4 \pi \in_{0}(r-x)^{2}}(-\hat{r})=9 * 10^{9} \frac{9 * 10^{-6} *\left(-1 * 10^{-6}\right)}{(r-x)^{2}}(-\hat{r})=\frac{81 * 10^{-3}}{(r-x)^{2}}(\hat{r})
$$

The negative sign of unit vector $r$ is because $q$ is on the left of $q_{2}$.

The distance $x$ is such that the net force is zero, hence we have
$\vec{F}_{1}+\vec{F}_{2}=0$
Or $\quad \frac{9 * 10^{-3}}{x^{2}}(-\hat{r})+\frac{81 * 10^{-3}}{(r-x)^{2}}(\hat{r})=0$
Gives $\frac{(r-x)^{2}}{x^{2}}=9$
Or $\quad \frac{(r-x)}{x}=3$
[taking appropriate positive sign only]
Gives $x=r / 4=50 / 4=12.5 \mathrm{~cm}$.
Hence $q$ will experience zero force at 12.5 cm from $\mathrm{q}_{1}$, towards $\mathrm{q}_{2}$.
(c) If the charge $\mathrm{q}_{2}$ is $-9 \mu \mathrm{C}$, it will repel q and hence for zero force q should be on the same side of $\mathrm{q}_{1}$ and $\mathrm{q}_{2}$. If it is at right of both, $\mathrm{q}_{2}$ (larger in magnitude) is nearer and $\mathrm{F}_{2}$ will be always greater than $\mathrm{F}_{1}$. Hence q must be on the left of both $\mathrm{q}_{1}$ and $\mathrm{q}_{2}$ as in figure. Force on q due to charge $\mathrm{q}_{1}$ will be

$$
\vec{F}_{1}=\frac{q_{1} q}{4 \pi \epsilon_{0} x^{2}}(-\hat{r})=9 * 10^{9} \frac{1 * 10^{-6} *\left(-1 * 10^{-6}\right)}{x^{2}}(-\hat{r})=\frac{9 * 10^{-3}}{x^{2}}(\hat{r})
$$

The negative sign of unit vector $r$ is because $q$ is on the left of $\mathrm{q}_{1}$.
And the force due to charge $\mathrm{q}_{2}$ will be (the distance or q from $\mathrm{q}_{2}$ is $\mathrm{r}+\mathrm{x}$ )

$$
\vec{F}_{2}=\frac{q_{2} q}{4 \pi \epsilon_{0}(r+x)^{2}}(-\hat{r})=9 * 10^{9} \frac{\left(-9 * 10^{-6}\right) *\left(-1 * 10^{-6}\right)}{(r+x)^{2}}(-\hat{r})=\frac{81 * 10^{-3}}{(r+x)^{2}}(-\hat{r}) \text { The }
$$

negative sign is because q is on the left of $\mathrm{q}_{2}$.
The distance x is such that the net force is zero, hence we have

$$
\vec{F}_{1}+\vec{F}_{2}=0
$$

Or $\quad \frac{9 * 10^{-3}}{x^{2}}(\hat{r})+\frac{81 * 10^{-3}}{(r+x)^{2}}(-\hat{r})=0$
Gives $\frac{(r+x)^{2}}{x^{2}}=9$
Or $\quad \frac{(r+x)}{x}=3$
[taking appropriate positive sign only]
Gives $x=r / 2=50 / 2=25.0 \mathrm{~cm}$.
Hence $q$ will experience zero force at 25.0 cm from $\mathrm{q}_{1}$, away from $\mathrm{q}_{2}$.
