

Q- Calculate the force required to pull a copper ball of radius 2.00cm upward through a fluid at the constant speed 9.00 cm/s. Take the drag force to be proportional to the speed, with proportionality constant 0.950 kg/s. Ignore the buoyant force.

The drag force is proportional to the speed and hence given by

$$F = k \cdot v \quad [\text{here } k \text{ is constant of proportionality}]$$

At a speed of 9.00 cm/s = 0.09 m/s the drag force will be

$$F = 0.950 \cdot 0.09 = 0.0855 \text{ N}$$

Let the external force with which the ball is pulled up is  $F_{\text{ext}}$  then the forces acting on the ball are

- (1) The external force  $F_{\text{ext}}$  upward
- (2) The weight  $mg$  of the ball downward and
- (3) the drag force  $F$  downward.

The mass of the ball is given by the product of its volume and the density hence

$$m = \frac{4}{3} \pi R^3 \cdot \rho = \frac{4}{3} \cdot 3.1416 \cdot (2.0 \cdot 10^{-2} \text{ m})^3 \cdot 8.96 \cdot 10^3 \text{ kgm}^{-3} = 0.300 \text{ kg}$$

$[(4\pi/3)R^3]$  is the volume of sphere and the density of copper can be found in the tables given in the books or search table on [www.wikipedia.org](http://www.wikipedia.org)

Hence the weight of the ball  $mg = 0.300 \cdot 9.8 = 2.94 \text{ N}$

Now under these three forces the ball is moving with constant velocity means that the forces are balanced and hence

$$F_{\text{ext}} - mg - F = 0$$

Or  $F_{\text{ext}} = mg + F = 2.94 + .0855 = 3.0255 \text{ N}$  upward.
