

Q- Light of wavelength 602.446 nm is used in a Michelson interferometer. When the mirror  $M_2$  is slowly moved, shifting of 33198 bright fringes is observed. By what distance mirror  $M_2$  is moved?

In Michelson interferometer when the mirror  $M_2$  is displaced the path difference between the two rays reaching the eye changes.

The maxima will be observed when the path difference between the rays from  $M_1$  and  $M_2$  is equal to integral multiple of wavelength  $\lambda$ , i.e.

$$\delta = n \lambda$$

If the mirror  $M_2$  is displaced by  $d$ , the path difference between the beams changes by  $2d$ . As the shift of one fringe (maximum to maximum) corresponds to a path difference of  $\lambda$  and hence the path difference corresponding to 33198 fringe shift will be  $33198 * \lambda$ . hence

$$2d = 33198 * \lambda$$

$$\text{Or } d = 33198 * \lambda / 2 = 16599 * 602.446 * 10^{-9} \text{ m}$$

$$\text{Or } d = 0.010000 \text{ m}$$
