Q- Two capacitors are connected to a battery with a two way swatch as shown in figure. The capacitors are initially uncharged. When the switch is thrown to the left the capacitor $C_{1}=10 \mu \mathrm{~F}$ is charged to 50 V . Now the switch is thrown to the right and the voltage across $\mathrm{C}_{1}$ is drops to 35 V .
(a) Find the value of $\mathrm{C}_{2}$.
(b) Find the final charge on each capacitor.

The capacitance of $\mathrm{C}_{1}=10 * 10^{-6} \mathrm{~F}$
The charge on the capacitor $\mathrm{C}_{1}$ when connected to 50 V batteries will be

$$
\mathrm{Q}=\mathrm{C}_{1} * \mathrm{~V}=10^{*} 10^{-6} * 50=5^{*} 10^{-4} \mathrm{C}
$$

When the switch is shifted to right the battery is disconnected and the two capacitors are now connected in parallel. The potential difference between the plates is equal and the charge is distributed between them.
(a) The charge remained on the $\mathrm{C}_{1}$ will be now

$$
\mathrm{Q}_{1}=\mathrm{C}_{1} \mathrm{~V}^{\prime}=10 * 10^{-6} * 35=3.5 * 10^{-4} \mathrm{C}
$$

Thus the charge on capacitor $\mathrm{C}_{2}$ will be

$$
\mathrm{Q}_{2}=\mathrm{Q}-\mathrm{Q}_{1}=5^{*} 10^{-4} \mathrm{C}-3.5^{*} 10^{-4} \mathrm{C}=1.5^{*} 10^{-4} \mathrm{C}
$$

As the two capacitors are now in parallel, the potential difference across $\mathrm{C}_{2}$ is also 35 V and hence its capacitance is given by

$$
\mathrm{C}_{1}=\mathrm{Q}_{2} / \mathrm{V}^{\prime}=1.5 * 10^{-4} / 35=\mathbf{4 . 2 9} * \mathbf{1 0}^{-6} \mathbf{F}
$$

(b) The charge on each capacitor is already calculated as

$$
Q_{1}=\mathbf{3 . 5 * 1 0 ^ { - 4 }} \mathbf{C}
$$

And $\mathrm{Q}_{2}=\mathbf{1 . 5} \boldsymbol{1 1 0}^{-4} \mathrm{C}$
