QQ- In the circuit bellow
(a) Find the equivalent resistance of the circuit.
(b) Find the currents $\mathrm{I}_{1}$ and $\mathrm{I}_{2}$.

(a) The three resistances between CD, DE and EF are in series (the same current through them) and their equivalent resultant will be $2+2+2=6 \Omega$.

This combination is in parallel with resistance $3 \Omega$ between CF and thus the resultant resistance between $C$ and $F$ will be given by

$$
R_{C F}=\frac{3 * 6}{3+6}=2 \Omega
$$

Thus, the circuit will reduce to the circuit given in the figure Now again in the same way the three resistances between $B C, C F$ and $F G$ are in series and their equivalent resultant will be $2+2+2=6 \Omega$.

This combination is in parallel with resistance $3 \Omega$ between BG and thus the resultant resistance between $B$ and $G$ will
 be given by

$$
R_{B G}=\frac{3 * 6}{3+6}=2 \Omega
$$

Thus, the circuit will reduce to the three resistances of $2 \Omega$ each in series with the cell and the equivalent resistance is given by

$$
R_{\text {eq }}=2+2+2=6 \Omega
$$

b) Here $\mathrm{I}_{1}$ is the total current through the circuit and as the emf of the cell is 12 V and the equivalent resistance of the circuit is 6 Ohm the current is given by Ohm's law as

$$
\mathrm{I}_{1}=\mathrm{V} / \mathrm{R}_{\mathrm{eq}}=12 / 6=2 \mathrm{~A}
$$

Now as the current $\mathrm{I}_{1}$ is distributed to two branches at B or resistances $6 \Omega$ and $3 \Omega$, if the potential difference between $B$ and $G$ is $V^{\prime}$ then using Ohms law again we get

$$
\begin{array}{ll} 
& \mathrm{V}^{\prime}=\mathrm{I}_{2} * 6=\left(\mathrm{I}_{1}-\mathrm{I}_{2}\right) * 3 \\
\text { Gives } & \mathrm{I}_{2} * 6=3 \mathrm{I}_{1}-3 \mathrm{I}_{2} \\
\text { Or } & 9 \mathrm{I}_{2}=3 \mathrm{I}_{1} \\
\text { Or } & \mathrm{I}_{2}=\mathrm{I}_{1} / 3=2 / 3=0.667 \mathrm{~A}
\end{array}
$$
