

Q- Q- A particle with mass 10 kg falls from a height of 1.5 m on a vertically mounted spring. If the spring constant is 4000 N/m, calculate the maximum compression in the spring.

Mass of the particle $m = 10 \text{ kg}$
 Height fallen before touching the spring $h = 1.5 \text{ m}$
 Spring constant $K = 4000 \text{ N/m}$

Let the maximum compression in the spring is ΔL , which is at the moment when the particle will just come to rest before moving up again. In this situation the loss is height of the particle will be $h + \Delta L$.

According to law of conservation of energy as the initial and final kinetic energy of the particle is zero we can write

Gain in elastic potential energy of spring = loss in gravitation potential energy

Or $\frac{1}{2} K (\Delta L)^2 = mg(h + \Delta L)^2$

Substituting the values we get

$$\frac{1}{2} * 4000 * \Delta L^2 = 10 * 9.8(1.5 + \Delta L)$$

Or $2000 \Delta L^2 = 147 + 98 \Delta L$

Or $2000 \Delta L^2 - 98 \Delta L - 147 = 0$

Or $\Delta L = \frac{-(-98) \pm \sqrt{(-98)^2 - 4 * 2000 * (-147)}}{2 * 2000}$

Or $\Delta L = \frac{98 \pm \sqrt{9604 + 1176000}}{2 * 2000} = \frac{98 \pm 1084.5}{2 * 2000}$

Or $\Delta L = \frac{98 \pm 1084.5}{2 * 2000} = 0.295 \text{ m}$ (cannot be negative thus + sign is taken)

Hence the compression in the spring will be 0.30 m or 30 cm.
